Discovery Of The Day: 17 Million Trees Okay, a bit of a twist. A while back, a scientist went through a bunch of photos from a glacier in southern Sweden and came across this image of two trees in the same snowbank. To their surprise, they realized that the trees had been growing during the entire Ice Age, and their existence was documented in the geological record. Now a team of geologists is carrying out a few more excavations in the same area, and they are expecting to find more such trees. That's a total of about 17 million trees, or about 140 million years of forestry. [New Scientist]Introduction {#sec1-1} ===== Rosai-Dorfman disease (RDD) is a rare, non-Langerhans, non-odontogenic, non-neoplastic, idiopathic, non-Lymphomatoid, histiocytic disorder of unknown etiology. [[@ref1]] CD68+ macrophages are primarily responsible for the diagnosis of RDD. [[@ref2]] CD68 positive cells are observed in the involved sinuses and in extravascular areas. Classical histological findings include heaped up lymphoid cells, histiocytes and emperipolesis. [[@ref3]] Clinically, patients with RDD often present with rapidly growing, painless or painful lymphadenopathy. Sinonasal extension is often seen in localized presentations, but also exists in cases of the common form. [[@ref4]] Case Report {#sec1-2} ===== A 2-year-old child presented to our outpatient clinic with a gradually enlarging anterior swelling in the right cheek since 2 months. The swelling was gradually increasing, was soft in consistency, fluctuant, and measuring approximately 10 cm x 6 cm in size. There was no associated pain, constitutional symptoms or any significant past history. An incisional biopsy was done and histopathological examination of the tissue revealed a dense lymphoid cell infiltrate containing numerous large histiocytes admixed with normal lymphocytes and plasma cells. In addition, atypical small mononuclear cells were noted. These cells did not show any immunohistochemical stain. The morphological features were suggestive of RDD. A
