Mr. Pierson and Mr. Storz I just noticed that you listed John Pierson and Steve Storz as the authors of the paper you cite in your response to the uncited paper by Les Morgan et al., which I wrote about on July 13. If you are going to include a reference to the work of somebody in your response to somebody else, you have to at least give them proper credit. The single most interesting and important thing about their work is that they discovered that if the tube of a gas chromatograph is not aligned in exactly the same orientation as the plates of a capillary column it has a temperature lag that can cause severe miscalculations. One can get a 100% accurate measurement by aligning the tube first, then the column, but this has led to a misunderstanding of the chemistry of ion-exchange separation. Until recently, most chromatographers have thought that a 2,000 cps pump was not a fast enough flow to get a good run. The pressure required is in the order of 8,000 psi and that's what the Wikipedia article says. John Pierson, however, at the behest of the Argonne National Laboratory, set about finding out just how fast a GC can be if you have a fast flowing stream of your mobile phase. He wanted to show that the output of the GC was dependent on flow rate, and in order to do so, he had to get his data down to the microsecond level. He did this by interfacing a high-speed photo diode array to a miniaturized temperature-controlled flow-through cell so that he could read the signal while he flowed the gas at different rates. After a whole bunch of iterations of improving the cell and detector and making up for the fact that the temperature of the cell was different from the temperature of the tubing, he concluded that flow rates of 10 to 100 microliters per minute are required to get good separation. As it happens, your high-speed detection equipment only works at a 100 picoliter per second, so you
